
[illegible]

Instructions are precise and
 rated by the attendant

The lecturer's instructions are precise and are well illustrated by the following examples: *King's mauls*, who prepare the different dishes to the eyes of the audience. Numbers of little grateful masters and mistresses bear witness to the improvement in the domestic bill of fare, and the hearing the discourse on hashes, for instance, should send to table tough chunks of meat or veal in greasy water or a thick floury mess, she would, deserve to be drummed out of the hall. He is to prepare a really beautiful and excellent *rechauffé* of a yesterday's roast. The gravy, having been carefully mixed, bottled, and strained, is allowed to get nearly cold before being poured over the meat, so that it may be reheated there to simmer as slowly as may be. Instead of slices of flabby toast, which too oftenicken the bread-winner sitting down to his dinner with work and hunger, the dish should be garnished with a few slices of bread shaved to a fine crisp toast in a water bath plunged into pan of boiling lard. As economy is the burden of the discourse, the thrifty manager is duly reminded that the scraps of the wire should be carefully reserved for other frying, but for nothing else to be used for fish. The virtue of cleanliness, exquisite and dainty cleanliness, ranks highly on the code of kitchen morality than even economy, and the lecturer is careful to insist on this point for himself. This is well indicated by the lecturer

court the recruit receives his day's pay—the

observe the ranks from which the ordinary class servant is recruited, her shortcomings cease to surprise us. It is no longer to the farm-house or tradesman's family, that look for servants who were the comfort and assistance of those who were themselves piano and dabble in 'logies. Too large a part of servants of the day are taken from squalid households where there is but little food to be cooked and household duties of any sort to be done. Girls of this home-bred type require training to perform the duties of a domestic servant, and in the main only at present acquire at the expense of their employers, and it is no wonder that clever, intelligent servant girl is as rare as a bird or a talking tree. It is as unreasonably to expect a girl to cook without having been properly instructed in the art, as it is to expect a watch, and this School of Cookery will be the parent of many others. That the nee

such establishments is felt may be inferred that the members of the committee have been several times in the city, and made many applications to organize similar schools, and a very rich landowners have offered to support any movement which will teach the children of the poor to cook and sew. Several of our countrymen have been busy and waking up to the knowledge that our riches we are an ill-fated nation, and have hoped half the advantages of our free trade, and the use of our own hands, and the people in want of a mission cannot do better go and learn at South Kensington how to profitable and palatable common man can be gotten and then go to the country where it knows this most useful knowledge.

GRAMME'S MAGNETO-ELECTRIC MACHINE.—Important and substantial step in advance has been in practical electricity by M. Gramme, of Paris substitutes a rotary for a reciprocating motion, mechanical arrangement employed in the production of an electrical current. Hietherto magneto machines have acted upon a principle analogous to that of the ordinary pump, and the current pro-

The new machine acts in a similar manner to the rotary pump, and, like that apparatus, produces a continuous stream, and with a very small expenditure of power, while the greater expenditure is locked to other systems, self-heating, is so backwardly appreciable. It is, moreover, the first recorded instance of a perfectly continuous stream of electricity being obtained on a practical scale, and the circumstances are of great interest from the fact that the inventor is a man of low rank of mechanical workers in electrical science, not a highly-educated electrician. Had he been so, the probability is that the present apparatus would never have been invented by him, for to produce a continuous stream, an electrician would have

the positive reasoning which would have landed us in an entirely opposite direction. Even Grahame's explanation of the reasons for producing the results he has achieved are at variance with the results of the experiment. His views entertained by electrical scientists, and the "production of the apparatus is therefore attributed more to intuition on the part of the inventor than to the study and practical application of the principles governing the production of electrical currents. The machine by means of this important improvement is effected in the form of three rings of soft iron encircled with a coil of copper wire. Each of these rings is rotated by each of the two other rings of the magnet. The magnets are vertical cylinders of iron, 3 feet 6 inches high by 31 inches in diameter and are coiled round with an insulated copper wire. The top of each magnet is mounted on a plate, and the bottom of each is mounted on a base 8 inches square. In operation the half of each which is in proximity with the north end of the magnet, takes south polarity, while the opposite half takes north polarity. The two opposite neutral points of the system are equivalent to the poles. The rings or bobbins are rotated on a horizontal axis, and when they are set in motion they remain unchanged in position with regard to the magnet. The two rings are connected to the coils alone being rotated over a star-shaped ring-shaped magnet. The effect of this produces currents in the two halves of each

opposite directions, between its two neutral points. At the same time, the machine was set to run in succession a series of strokes consisting of regular intervals, with the wire coil. Thus the site currents in the two halves of each ring, is neutralizing each other, unite and form a single stroke. This requires a very small quantity of force to drive it—much less than that required by simple—and it produces a very steady flow of light. With this some interesting experiments have lately been made by Mr. Robert Sabine, of the Ordnance Office, in connection with the works of Messrs. Westman and Co., of Westminster-bridge road, where the machine was first manufactured. It was shown that the is producible in large quantities, at a much rate, and of greater constancy than by any other means. It was also shown that the machine was also demonstrated in the fact that the resistance was the same no matter at what speed the is driven within reasonable limits. Thereby driving it at double speed twice as much as the force is increased, was required to produce, more than twice as much current. In the experiments the machine was driven at a rate of about 320 revolutions per minute, and the first object of the exhibitors was to make the light produced by the system. In a single place a length of 10 feet of platinum wire, red-hot in a few seconds. This experiment was afterwards repeated with a chain of about six inches and composed of alternate links, six of same metal and six of platinum. While the platinum became red-hot, and immediately cooled, the iron became more than inconspicuously heated. This producing power of the apparatus was then seen from the rear portion of Messrs. Whieldon's. The light was produced in the usual way, by carbon points, and the light was produced by which threw the rays down a corridor of the premises in the York-road, a long distance, which were brilliantly lighted up. The light

[illegible]

is driven within reasonable limits, driving it at double speed

opportunity of judging of its merits.

1. The Commission has received information from the Government of the United Kingdom that the Government of the United Kingdom has decided to withdraw its troops from the Falkland Islands and to transfer the Islands to the Government of Argentina.

[illegible][illegible][illegible]

1. The first step in the process is to identify the problem or issue that needs to be addressed. This involves gathering information and understanding the context of the problem.

2. Once the problem is identified, the next step is to define the objectives and goals of the project. This helps to clarify what needs to be achieved and provides a clear direction for the team.

3. The third step is to develop a plan or strategy to address the problem. This involves breaking down the problem into smaller, manageable tasks and determining the resources needed to complete each task.

4. The fourth step is to implement the plan. This involves putting the strategy into action and monitoring progress to ensure that the project is on track.

5. The final step is to evaluate the results of the project. This involves assessing the outcomes against the objectives and goals and identifying any areas for improvement.

[illegible]
